

# WeatherPy

- Observation 1: As the city gets closer to equator, the temperature does look like it tends to rise. For the most part, there are trend looks to increase as it goes to zero from both the southern side and northern side.
- Observation 2: In the northern hemisphere, greater latitudes, it seems like there is a wider range of humidity percentages where as the southern hemisphere seems to be more highly concentrated toward the 100% humidity.
- Observation 3: There is definitely some selection errors or bias that are possible. The method I used to select the cities used the `nearest_city` function. The `nearest_city` function looks at the coordinates and finds the closest city. This means that if a city is in isolation and not near any other city, the city could be randomly selected using a wider variety of coordinates. This method of selecting data could be improved if we knew all the cities in the weather database and then randomly selecting a city from that population to ensure that it is more randomly selected.
